When do we need VM?

1. Working on multiple projects with different SDK version requirements.
2. Testing compatibility with new releases without impacting existing projects.
3. Collaborating with teams to maintain consistency in the SDK versions.
4. Exploring and evaluating new features and improvements.

What is package manager?

A **package manager** is a tool that automates the process of installing, updating, configuring, and removing software packages in an operating system. It simplifies software management by handling dependencies, ensuring compatibility, and providing version control.

Importance of a PM

Simplifies Software Installation – Eliminates the need for manual downloads and installations.

Dependency Management – Ensures all required dependencies are installed automatically.

Version Control – Allows installation of specific versions and rollback to previous versions.

Security & Integrity – Verifies software authenticity and prevents tampering.

System Efficiency – Reduces disk space usage by avoiding redundant libraries.

Automated Updates – Keeps software up-to-date without manual intervention.
